C2 W2 lecture

September 4, 2021

1 Week 2 lecture notebook

1.1 Outline

Section ??

Section ??

Section ??

Section ??

Missing values

```
[1]: import numpy as np import pandas as pd
```

```
[2]: feature_1 feature_2
0 0.1 1.1
1 NaN 2.2
2 NaN NaN
3 0.4 NaN
```

1.1.1 Check if each value is missing

```
[3]: df.isnull()
```

```
[3]: feature_1 feature_2
0 False False
1 True False
2 True True
3 False True
```

1.1.2 Check if any values in a row are true

- [4]: col_1 col_2
 0 True True
 1 True False
 2 False False
 - If we use pandas.DataFrame.any(), it checks if at least one value in a column is True, and if so, returns True.
 - If all rows are False, then it returns False for that column
- [5]: df_booleans.any()
- [5]: col_1 True col_2 True dtype: bool
 - Setting the axis to zero also checks if any item in a column is True
- [6]: df_booleans.any(axis=0)
- [6]: col_1 True col_2 True dtype: bool
 - Setting the axis to 1 checks if any item in a row is True, and if so, returns true
 - Similarly only when all values in a row are False, the function returns False.
- [7]: df_booleans.any(axis=1)
- [7]: 0 True 1 True 2 False dtype: bool

1.1.3 Sum booleans

```
[8]: series_booleans = pd.Series([True,True,False])
series_booleans
```

[8]: 0 True 1 True

```
2 False dtype: bool
```

• When applying sum to a series (or list) of booleans, the sum function treats True as 1 and False as zero.

```
[9]: sum(series_booleans)
```

[9]: 2

You will make use of these functions in this week's assignment!

1.1.4 This is the end of this practice section.

Please continue on with the lecture videos!

Decision Tree Classifier

```
[10]: import pandas as pd
[11]: X = pd.DataFrame({"feature_1":[0,1,2,3]})
y = pd.Series([0,0,1,1])
[12]: X
```

```
[12]: feature_1
0 0
1 1
2 2
3 3
```

```
[13]: y
```

```
[13]: 0     0
     1     0
     2     1
     3     1
     dtype: int64
```

```
[14]: from sklearn.tree import DecisionTreeClassifier
```

```
[15]: dt = DecisionTreeClassifier()
dt
```

[15]: DecisionTreeClassifier(ccp_alpha=0.0, class_weight=None, criterion='gini', max_depth=None, max_features=None, max_leaf_nodes=None,

```
min_impurity_decrease=0.0, min_impurity_split=None,
min_samples_leaf=1, min_samples_split=2,
min_weight_fraction_leaf=0.0, presort='deprecated',
random_state=None, splitter='best')
```

```
[16]: dt.fit(X,y)
```

1.1.5 Set tree parameters

1.1.6 Set parameters using a dictionary

- In Python, we can use a dictionary to set parameters of a function.
- We can define the name of the parameter as the 'key', and the value of that parameter as the 'value' for each key-value pair of the dictionary.

• We can pass in the dictionary and use ** to 'unpack' that dictionary's key-value pairs as parameter values for the function.

```
[19]: dt = DecisionTreeClassifier(**tree_parameters)
dt
```

```
[19]: DecisionTreeClassifier(ccp_alpha=0.0, class_weight=None, criterion='entropy',
                              max_depth=10, max_features=None, max_leaf_nodes=None,
                              min_impurity_decrease=0.0, min_impurity_split=None,
                              min_samples_leaf=1, min_samples_split=2,
                              min_weight_fraction_leaf=0.0, presort='deprecated',
                              random_state=None, splitter='best')
     1.1.7 This is the end of this practice section.
     Please continue on with the lecture videos!
     \#\# Apply a mask
     Use a 'mask' to filter data of a dataframe
[20]: import pandas as pd
[21]: df = pd.DataFrame({"feature_1": [0,1,2,3,4]})
      df
[21]:
         feature_1
      0
      1
                  1
      2
                 2
      3
                 3
                 4
[22]: mask = df["feature_1"] >= 3
      mask
[22]: 0
           False
           False
      1
           False
      2
      3
            True
      4
            True
      Name: feature_1, dtype: bool
[23]: df [mask]
[23]:
         feature 1
      3
                 3
```

4

1.1.8 Combining comparison operators

You'll want to be careful when combining more than one comparison operator, to avoid errors. - Using the and operator on a series will result in a ValueError, because it's

```
[24]: df["feature_1"] >=2
[24]: 0
                                          False
                                          False
                       1
                       2
                                             True
                       3
                                              True
                       4
                                              True
                       Name: feature_1, dtype: bool
[25]: df["feature_1"] <=3
[25]: 0
                                              True
                                              True
                       1
                       2
                                              True
                       3
                                             True
                                         False
                      Name: feature_1, dtype: bool
[26]: # NOTE: This will result in a ValueError
                       df["feature_1"] >=2 and df["feature_1" ] <=3</pre>
                                                   ValueError
                                                                                                                                                                                                                      Traceback (most recent call_
                        →last)
                                                   <ipython-input-26-4feb82af6b46> in <module>
                                                           1 # NOTE: This will result in a ValueError
                                    ----> 2 df["feature_1"] >=2 and df["feature_1"] <=3
                                                    /opt/conda/lib/python3.7/site-packages/pandas/core/generic.py in in in in in in in items in 
                        →__nonzero__(self)
                                                                                                                  "The truth value of a {0} is ambiguous. "
                                                1553
                                                                                                                  "Use a.empty, a.bool(), a.item(), a.any() or a.all().".
                                                1554
                        →format(
                                    -> 1555
                                                                                                                                 self.__class__.__name__
                                                1556
                                                                                                  )
                                                1557
```

```
ValueError: The truth value of a Series is ambiguous. Use a.empty, a. →bool(), a.item(), a.any() or a.all().
```

1.1.9 How to combine two logical operators for Series

What we want is to look at the same row of each of the two series, and compare each pair of items, one row at a time. To do this, use: - the & operator instead of and - the | operator instead of or. - Also, you'll need to surround each comparison with parenthese (...)

```
[27]: # This will compare the series, one row at a time
  (df["feature_1"] >=2) & (df["feature_1"] <=3)</pre>
```

```
[27]: 0 False
    1 False
    2 True
    3 True
    4 False
    Name: feature 1, dtype: bool
```

1.1.10 This is the end of this practice section.

Please continue on with the lecture videos!

Imputation

We will use imputation functions provided by scikit-learn. See the scikit-learn documentation on imputation

```
[28]: import pandas as pd import numpy as np
```

```
[29]:
           feature_1
                        feature_2
       0
                     0
                               0.0
       1
                     1
                               NaN
       2
                     2
                              20.0
       3
                     3
                              30.0
                     4
       4
                              40.0
       5
                     5
                              50.0
                     6
       6
                              60.0
                     7
                              70.0
```

```
8 8 80.0
9 9 NaN
10 10 100.0
```

1.1.11 Mean imputation

```
[30]: from sklearn.impute import SimpleImputer
[31]: mean_imputer = SimpleImputer(missing_values=np.NaN, strategy='mean')
     mean_imputer
[31]: SimpleImputer(add_indicator=False, copy=True, fill_value=None,
                   missing_values=nan, strategy='mean', verbose=0)
[32]: mean_imputer.fit(df)
[32]: SimpleImputer(add_indicator=False, copy=True, fill_value=None,
                   missing_values=nan, strategy='mean', verbose=0)
[33]: nparray_imputed_mean = mean_imputer.transform(df)
     nparray_imputed_mean
[33]: array([[ 0.,
                     0.],
             1.,
                    50.],
             2.,
                    20.],
             3.,
                    30.],
             4.,
                    40.],
               5.,
                    50.],
                    60.],
             Γ
               6.,
             [ 7., 70.],
             [ 8., 80.],
             [ 9., 50.],
             [ 10., 100.]])
```

Notice how the missing values are replaced with 50 in both cases.

1.1.12 Regression Imputation

```
[34]: from sklearn.experimental import enable_iterative_imputer
from sklearn.impute import IterativeImputer

[35]: reg_imputer = IterativeImputer()
reg_imputer
```

```
[35]: IterativeImputer(add_indicator=False, estimator=None,
                       imputation_order='ascending', initial_strategy='mean',
                      max iter=10, max value=None, min value=None,
                      missing_values=nan, n_nearest_features=None, random_state=None,
                       sample posterior=False, skip complete=False, tol=0.001,
                       verbose=0)
[36]: reg_imputer.fit(df)
[36]: IterativeImputer(add_indicator=False, estimator=None,
                       imputation_order='ascending', initial_strategy='mean',
                      max_iter=10, max_value=None, min_value=None,
                      missing_values=nan, n_nearest_features=None, random_state=None,
                       sample posterior=False, skip complete=False, tol=0.001,
                       verbose=0)
[37]: nparray_imputed_reg = reg_imputer.transform(df)
      nparray_imputed_reg
               0.,
[37]: array([[
                     0.],
                     10.],
             1.,
             2.,
                     20.],
             3.,
                    30.],
             4.,
                     40.],
                    50.],
             Γ
               5..
             6.,
                     60.],
             Γ
               7.,
                    70.],
               8.,
                    80.],
             [ 9., 90.],
             [ 10., 100.]])
```

Notice how the filled in values are replaced with 10 and 90 when using regression imputation. The imputation assumed a linear relationship between feature 1 and feature 2.

1.1.13 This is the end of this practice section.

Please continue on with the lecture videos!
